Module 12:
Opinion Mining

What is Opinion Mining?

- OM is a recent discipline that studies the extraction of opinions using IR, AI and/or NLP techniques.

- More informally, it's about extracting the opinions or sentiments given in a piece of text

- Also referred to as Sentiment Analysis (though technically this is a more specific task)

- Web 2.0 nowadays provides a great medium for people to share things.

- This provides a great source of unstructured information (especially opinions) that may be useful to others (e.g. companies and their rivals, other consumers...)

It's about finding out what people think...

...and then exposing insights

What they were all talking about...

Online social media sentiment apps

- There are lots of these apps available:
    - Twitter sentiment http://twittersentiment.appspot.com/
    - Twends: http://twendz.waggeneredstrom.com/
    - Twittratr: http://twitrratr.com/
    - SocialMention: http://socialmention.com/
- Easy to search for opinions about famous people, brands and so on
- Hard to search for more abstract concepts, perform a non-keyword based string search

Opinion Mining is Big Business

- Someone who wants to buy a camera

  - Looks for comments and reviews

- Someone who just bought a camera

  - Comments on it

  - Writes about their experienc

- Camera Manufacturer

  - Gets feedback from custom

  - Improve their products

  - Adjust Marketing Strategies

Related (sub)topics: general

- **Opinion extraction**: extract the piece of text which represents the opinion

  - I just bought a new camera yesterday. <u>It was a bit expensive, but the battery life is very good.</u>

- **Sentiment classification/orientation:** extract the polarity of the opinion (e.g. positive, negative, neutral, or classify on a numerical scale)

  - negative: <u>expensive</u>

  - positive: <u>good battery life</u>

- **Opinion summarisation**: summarise the overall opinion about something

  - price:negative, battery life: positive --> overall 7/10

Feature-opinion association

- **Feature-opinion association**: given a text with target features and opinions extracted, decide which opinions comment on which features.

    - "The battery life is good but not so keen on the picture quality"

- **Target identification**: which thing is the opinion referring to?

- **Source identification**: who is holding the opinion?

- There may be attachment and co-reference issues

    - "The camera comes with a free case but I don't like the colour much."

    - Does this refer to the colour of the case or the camera?

Opinion spamming

Suppose we run a contest where people retweet our ad repeatedly, and the winner's whoever loses the most followers.

Spam opinion detection

- **Spam opinion detection**: detect whether opinions are written by spammers

- Could involve language analysis, frequency analysis,..

- Could be either positive or negative opinions

- Generally, negative opinions are more damaging than positive ones

- Spam opinions are typically posted by the same person on multiple sites and/or threads with identical or very similar wording

- Sometimes people get paid to post "spam" opinions supporting a product, organisation or even government: typically these are easily detectable due to their similarity and frequency

- Look for **outlier** reviews (which go against the trend)

It's not just about cameras and dresses ...

- Film, theatre, books, fashion etc
    - impacts on the whole industry
    - predictions about changing society, trends etc.
- Monitoring political views
- Feedback/opinions about multimedia productions, e.g. documentaries, broadcasts etc.
- Feedback about events, e.g. conferences
- Scientific and technological monitoring, competitor surveillance etc.
- Monitoring public opinion
- Creating community memories

And it's not always as easy as it looks...

"Rubbish hotel in Madrid"

Deep sentiment analysis

- The hardest thing about getting sentiment analysis right is uncovering exactly what is being meant

- Difference between a customer saying they merely like a brand and saying that they love it.

- Sentiment has many rich and nuanced dimensions that need to be teased apart to make it insightful.

- "An old lady told me that warm Dr. Pepper is delicious"

  - Is it only nice when warm?

  - Does the author share the opinion of the old lady?

  - Could this be a new insight for the manufacturers/advertisers?

- "I loved Dr. Pepper because of Dude." (Dude was a character in the ad)

  - Does the author still like Dr Pepper?

  - Should the manufacturers consider bringing back the commercial?

- Classification of sentiment according to functional, insightful, emotional etc.

The Ultimate Question

- The book "The Ultimate Question" recently ranked #1 on the Wall Street Journal's Business Best-Sellers List and #1 on USA TODAY's Money Best-Sellers List.

- It's all about whether a consumer likes a brand enough to recommend it.

- This apparently is the key to a company's performance.

- General sentiment detection isn't precise enough to answer this kind of question, because all kinds of "like" are treated equally

- Growing need for sentiment analysis that can get to very fine levels of detail, while keeping up with the enormous (and constantly increasing) volume of social media.

Opinion mining and social media

- Social media provides a wealth of information about a user's behaviour and interests:

  - *explicit*: John likes tennis, swimming and classical music

  - *implicit*: people who like skydiving tend to be big risk-takers

  - *associative*: people who buy Nike products also tend to buy Apple products

- While information about individuals isn't useful on its own, finding defined clusters of interests and opinions is

  If many people talk on social media sites about fears in airline security, life insurance companies might consider opportunities to sell a new service

- This kind of predictive analysis is all about understanding your potential audience at a much deeper level - this can lead to improved advertising techniques such as personalised ads to different groups

Analysing and preserving opinions

- Useful to collect, store and later retrieve public opinions about events and their changes or developments over time

- One of the difficulties lies in distinguishing what is important

- Opinion mining tools can help here

- Not only can online social networks provide a snapshot of such situations, but they can actually trigger a chain of reactions and events

- Ultimately these events might lead to societal, political or administrative changes

Pippa Middleton's assets

- One of the biggest Royal Wedding stories on Social Media sites

- Her bottom has its own twitter account, facebook page and website.

- Pilates classes have become incredibly popular since the Royal Wedding, solely as a result of all the social media

Pippa Middleton has revealed the secret to her perfect figure - Pilates classes. http://dlvr.it/S9Cy8

CutePippaFace: 57 minutes ago.   Reply View Tweet

Accuracy of twitter sentiment apps

- Mine the social media sentiment apps and you'll find a huge difference of opinions about Pippa Middleton:

- TweetFeel: 25% positive, 75% negative

- Twendz: no results

- TipTop: 42% positive, 11% negative

- Twitter Sentiment: 62% positive, 38% negative

Tracking opinions over time

- Opinions can be extracted with a time stamp and/or a geo-location

- We can then analyse changes to opinions about the same entity/event over time, and other statistics

- We can also measure the impact of an entity or event on the overall sentiment about an entity or another event, over the course of time (e.g. in politics)

- Also possible to incorporate statistical (non-linguistic) techniques to investigate dynamics of opinions, e.g. find statistical correlations between interest in certain topics or entities/events and number/impact/influence of tweets etc.
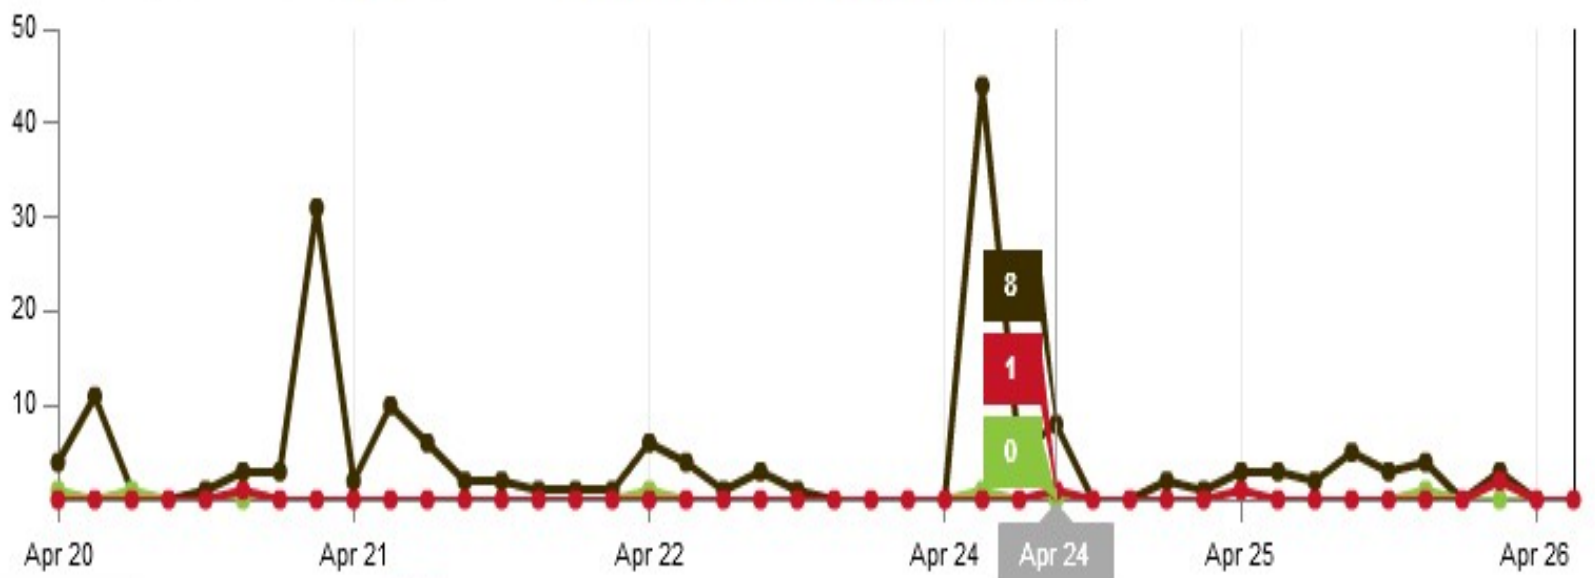

Viewing opinion changes over time

All opinions are not equal

- Opinion Mining needs to take into account how much influence any single opinion is worth

- This could depend on a variety of factors, such as how much trust we have in a person's opinion, and even what sort of person they are

- Need to account for:

  - experts vs non-experts

  - spammers

  - frequent vs infrequent posters

  - "experts" in one area may not be expert in another

  - how frequently do other people agree?

Trust Recommenders

- Two types of trust:

    - relationship (local) trust

    - reputation (global) trust.

- **Relationship trust**: if you and I both rate the same things, and our opinions on them match closely, we have high relationship trust. This can be extended to a social networking group --> web of trust.

- **Reputation trust**: if you've recommended the same thing as other people, and usually your recommendation is close to what the majority of people think, then you're considered to be more of an expert and have high reputation trust.

- We can extend relationship trust to form clusters of interests and likes/dislikes

- We can narrow reputation trust to opinions about similar topics

Rule-based Opinion Mining from Political Tweets

Processing political tweets

- Application to associate people with their political leanings, based on pre-election tweets

- First stage is to find triple <Person, Opinion, Political Party>

  - e.g. John Smith is pro_Labour

- Usually, we will only get a single sentiment per tweet

- Later, we can collect all mentions of "John Smith" that refer to the same person, and collate the information

  - For example, John may be equally in favour of several different parties, not just Labour, but hates the Conservatives above all else

Creating a corpus

- First step is to create a corpus of tweets

- Used the Twitter Streaming API to suck up all the tweets over the pre-election period according to various criteria (e.g. use of certain hash tags, mention of various political parties etc.)

- Collected tweets in json format and then converted these to xml using JSON-:ib library

- This gives us lots of additional twitter metadata, such as the date and time of the tweet, the number of followers of the person tweeting, the location and other information about the person tweeting, and so on

- This information is useful for disambiguation and for collating the information later

Corpus Size

- Raw corpus contained around 5 million tweets

- Many were duplicates due to the way in which the tweets were collected

- Added a de-duplication step during the conversion of json to xml

- This reduced corpus size by 20% to around 4 million

- This still retains the retweets, however

Tweets with metadata

Profile info

Name

Gazetteers

- We create an instance of a flexible gazetteer to match certain useful keywords, in various morphological forms:

  - political parties, e.g. "Conservative", "LibDem"

  - concepts about winning election, e.g. "win", "landslide"

  - words for politicians, e.g. "candidate", "MP"

  - words for voting and supporting a party/ person, e.g. "vote"

  - words indicating negation, e.g. "not", "never"

- We create another gazetteer containing affect/emotion words from WordNet.

  - these have a feature denoting part of speech (category)

  - Keeping category information may be important, so we don't want a flexible gazetteer here

Grammar rules: creating temporary annotations

- Identify questions or doubtful statements as opposed to "factual" statements in tweets.

- Initially, we just look for question marks
    - *"Wont Unite's victory be beneficial to Labour?"*

- Create temporary Affect annotations if an "affect" Lookup is found and if the category matches the POS tag on the Token (this ensures disambiguation of the different possible categories)
    - *"Just watched video about <u>awful</u> days of Tory rule" vs "Ah <u>good</u>, the entertainment is here."*
    - *"People <u>like</u> her should be shot." vs "People <u>like</u> her."*

Question grammar

Phase: Preprocess

Input: Token

Options: control = appelt

Rule: Question

(

 {Token.string == "?"}

):tag

-->

:tag.Question = {rule = "Question"}

Affect grammar

Phase: Affect

Input: AffectLookup Token

Options: control = appelt

Check category of both Lookup and Token
are adjectives or past participles

Rule: AffectAdjective

(

{AffectLookup.category == adjective,Token.category == VBN}|

{AffectLookup.category == adjective, Token.category == JJ}

):tag

-->

copy category and kind
values from Lookup to new
Affect annotation

:tag.Affect = {kind = :tag.AffectLookup.kind,

category = :tag.AffectLookup.category,

rule = "AffectAdjective"}

Grammar rules: finding triples

- We first create temporary annotations for Person, Organization, Vote, Party, Negatives etc. based on gazetteer lookup, NEs etc.

- We then have a set of rules to combine these into pairs or triples:

  - *<Person, Vote, Party> "Tory Phip admits he voted LibDem".*

  - *<Party, Affect> "When they get a Tory government they'll be sorry."*

- We create an annotation "Sentiment" which has the following features:

  - kind = "pro_Labour", "anti_LibDem", etc.

  - opinion_holder = "John Smith", "author" etc.

Identifying the Opinion Holder

- If the opinion holder in the pattern matched is a Person or Organization, we just get the string as the value of opinion_holder

- If the opinion holder in the pattern matched is a pronoun, we first find the value of the string of the antecedent and use this as the value of opinion_holder

- Currently we only match opinion holders within the same sentence.

- If no explicit opinion holder then we use "author" as the value of opinion_holder.

- Later we can grab the details of the twitterer instead of just using "author".

Grammar rules: finding antecedents

- Find the antecedents of pronouns within a sentence so that we can refer a sentiment back to the original opinion holder or object of the opinion.

- First run the pronominal coreference PR

- Then use a JAPE rule to find pronouns linked to a Person or Organization

- We can identify these because they will have the feature "ENTITY_MENTION_TYPE" (created by the coreferencer)

- The co-referring pronouns all have also an antecedent_offset feature pointing to the proper noun antecedent

- The matching proper noun antecedent is found and its string is added as a feature on the relevant pronoun annotation

Implicit Opinion Holders

- There may not always be an explicit opinion holder

- In many cases, the author of the tweet is the opinion holder

    - *I'm also going to vote Tory. Hello new world."*

    - Here we can co-refer "I" with the person tweeting (using the metadata)

- In other cases, there is no explicit opinion holder:

    - *"Vote for Labour. Harry Potter would."*

    - However, we can infer by this instruction that the author of the tweet shares this opinion.

- In all these cases, we add the value "author" to the feature "opinion_holder"

Creating the Application

- We only want to process the actual text of the tweet, not all the other information

- To do this, we use a Segment Processing PR to run the sentiment app over just the "text" annotation in Original Markups set.

- So, we need two applications: one containing the Segment Processing PR and one containing the actual sentiment application

Runtime Parameters for the "Segment Processing PR_0001E" Segment Processing PR:

Name	Type	Required	Value
(?) controller	CorpusController	✓	⚙ twitter app
(?) inputASName	String		Original markups
(?) segmentAnnotationType	String	✓	text

Hands-on 1: Analysing political tweets

- Load the ANNIE, Tools and Alignment plugins
- Load the document corpus/politwits-smiley.xml from the hands-on material and add it to a corpus
- Load the application resources/sentiment-all.gapp
- This should also load the sentiment-processing application
- Run sentiment-all.gapp on the corpus and look at the results
- Tip: Make sure you run the right application
- Click on **Sentiment** to see the overall Sentiment of the tweet
  - Sentiment.kind should be **pro-Con**
- Click on **Party** and **Vote** to see intermediate annotations

Hands-on 2: Modifying the application

- Task: modify the application to annotate the following sentence as "anti_Tory":

  - *They all voted Tory* :-(

- Step 1: add the emoticon as a new entry in the affect gazetteer list affect_sadness.lst, with feature "category" and value "smiley"

- Step 2: add a new rule in the affect.jape grammar to create an Affect annotation from an AffectLookup with category=smiley

- Reinitialise grammar and gazetteer and rerun the application

- **Sentiment.kind** should now be **anti-Con** instead of **pro-Con**

Hands-on 3: Using ANNIC

- Create a new Lucene datastore in GATE

- Use default parameters, except set "AnnotationSets" parameter to exclude "Key"

- Create a new empty corpus, save it to the datastore, then populate it with the politwits-500 corpus (you may need to unzip it first)

- Run the application on the corpus (this may take a little while)

- Select "Lucene datastore searcher" from the datastore viewer

- Try out some patterns to see what results you get: if you find a pattern that enables you to find an opinion, try implementing it in a JAPE grammar

- Look for negative words in the tweets, and add some new gazetteer entries and/or grammar rules to deal with these.

Hands-on 3: Pattern examples

- Try thinking up your own patterns, but here are some you can try out to get you started (try changing the number of Tokens, or adding negatives):

- {Lookup.majorType == negation} ({Token})*4 {Lookup.majorType == "vote"}{Lookup.majorType == "party"}

- {Token.string == "I"} ({Token})*4 {Lookup.majorType == "vote"} {Lookup.majorType == "party"}

- {Person} ({Token})*4 {Lookup.majorType == "vote"} {Lookup.majorType == "party"}

- {Affect}   ({Token})*5   {Lookup.majorType == "candidate"}

- {Vote} ({Token})*5   {Lookup.majorType == "candidate"}

Linguistic information for better analysis

- Linguistic information can give you a lot of clues about meaning

- "Good battery life" seems to indicate a positive feature.

- But conditional sentences can have subtly different meanings:

    - *I'd have bought a Nikon if I'd wanted good battery life*

    - *I'll buy a Nikon if it has good battery life*

    - *I'll buy a Nikon if I want good battery life*

    - *I'd buy a Nikon unless I wanted good battery life*

    - *I'd buy a Nikon even if it doesn't have good battery life.*

Conditional Types

0. If a camera has 20 hours of battery life, you can take many pictures.

   - statement of fact or certainty

1. If someone makes a camera with 20 hours of battery life, I'll buy it

   - potential conditional
   - *long battery life is my top priority*

2. If someone made a camera with 20 hours of battery life, I'd buy it

   - less probably conditional. Indicates preference
   - *as (1), but I think it's unrealistic so I'll settle for something else*

3. If someone had made a camera with 20 hours of battery life, I'd have bought it

   - Impossible past events
   - *as (1), but they don't make one, so I bought something else*

More examples

2. If I wanted a camera with 20 hours of battery life, I would buy a Nikon

- *battery life is not my priority, so I'll probably buy something else*

3. If I had wanted a camera with 20 hours of battery life, I'd have bought a Nikon

- *battery life is not my priority and so I bought something other than Nikon*

Linguistic analysis of conditional types

Type 0: If + simple present --> simple present

- *If it has good battery life, you can take lots of pictures*

Type 1: If + simple present --> simple future

- *If it has good battery life, I will buy it*

Type 2: If + past --> would + infinitive

- *If it had good battery life, I would buy it*

Type 3: If + past perfect --> present perfect

- *If it had had good battery life, I would have bought it*

Simple conditional application in GATE

- Gazetteer list gives us words associated with conditionals
  - if, assuming, even if, as long as, on condition that... (positive)
  - unless (negative)
- Verb chunker segments the VPs and also gives
  - the tense of the verb
  - active or passive
  - positive or negative
- Grammar rules combine items from gazetteer with verb information to create rules for sentences

Sample grammar for type 0 conditional

Input: Split VG ConditionalIndicator

Pattern: If + simple present, simple present

Rule: Conditional0

(

{ConditionalIndicator}

{Lookup.majorType == conditional}

{VG.tense == SimPre}

Verb phrases with verb in the simple present tense

{VG.tense == SimPre}

{Split}

Don't let the pattern span a sentence boundary

):tag

-->

:tag.Conditional = {type = "0"}

Tag the whole sentence as a conditional of type 0

Why do we do the Lookup in a separate phase?

- Why do we first find the Conditional Lookups and annotate them separately? Why not just use the Lookup annotation within the rule?

- The clue is in the Input headers

- If we use a Lookup annotation within the rule, we need to add "Lookup" to the Input headers

- What effect might this have on the rule?

- Remember that we only want to state explicitly in the rule the things we care about.

- We don't care (at this stage) which nouns occur in the sentence so we want to leave as much as possible unspecified.

Hands-on 3: conditionals

- Remove all loaded applications and documents from GATE

- Load the application resources/conditionals.gapp from the hands-on materials

- Load the text corpus/conditional-sentences.txt, add to a corpus and run the application on it

- Check the results

- Have a look at the grammar conditional-polarity.jape and see if you can work out how the negation part works

- Can you work out why sentence 6 has the wrong polarity?

Negation: adding the polarity feature

- The sentence is divided into its two verb phrases: firstPol and secondPol

- For each phase, if the value of the neg feature is "yes", then "neg" is stored as the new value

- If the value of the neg feature is "no", then "pos" is stored as the new value

- A new feature called "polarity" is added to the final annotation that covers the whole sentence

- The values of the two neg features (one for each VP) are added consecutively as the values of polarity, e.g. "neg" + "pos"

Machine Learning for Sentiment Analysis

- ML is an effective way to classify opinionated texts

- We want to train a classifier to categorize free text according to the training data.

- Good examples are consumers' reviews of films, products, and suppliers.

- Sites like www.pricegrabber.co.uk show reviews and an overall rating for companies: these make good training and testing data

- We train the ML system on a set of reviews so it can learn good and bad reviews, and then test it on a new set of reviews to see how well it distinguishes between them

- We give an example of a real application we developed for a previous project, and some related hands-on for you to try

Examples of consumer reviews

Reviews

Jessops not only failed to complete the next day delivery, the item sent, a digital picture frame did not meet their specification. We ordered it as they claimed on their website that it accepted XD cards. This however was not the case. Jessops felt that they had done nothing wrong although their website was obviously wrong. This incorrect information still is outstanding and they have done nothing to correct their website even though I have notified them of the error.

Overall Rating
★☆☆☆☆

Preparing the corpus

- Corpus of 40 documents containing 552 company reviews.

- Each review has a 1- to 5-star rating.

- We pre-processed these in GATE to label each review with a comment annotation with a rating feature (free manual annotation!)

- In ML terms:

    - instance = *comment* annotation

    - class = *rating* feature on the *comment* annotation

    - attributes = NLP features of the underlying text

- We will keep the spans of the comment annotations and use ML to classify them with the *rating* feature

Annotated review

Developing the training application

- We will develop an application that runs a set of NLP components to provide ML instance attributes, and train the classifier

- Take the config file **ml-exercise/paum.xml** from the hands-on materials and copy it to a writable directory on your machine.

- The Batch Learning PR needs to create a **savedFiles** directory and write inside that.

- Load the ANNIE, Tools, and Learning plugins.

- Create a new corpus called "training" and populate it from the directory **ml-exercise/corpora/training** in the hands-on material

Batch learning config (paum.xml)

```
<PARAMETER name="thresholdProbabilityClassification"
            value="0.5"/>
```

- This threshold will probably produce a class for each instance

- Classification problems do not use the other threshold probability parameters

```
<multiClassification2Binary method= "one-vs-others"/>
```

- this is much faster than one-vs-another

```
<ENGINE nickname="PAUM" implementationName="PAUM"
        options=" -p 50 -n 5 -optB 0.0  "/>
```

- Perceptron with uneven margins

- default options

Batch learning config (2)

```
<INSTANCE-TYPE>comment</INSTANCE-TYPE>

<ATTRIBUTE>
<NAME>Class</NAME>
<SEMTYPE>NOMINAL</SEMTYPE>
<TYPE>comment</TYPE>
<FEATURE>rating</FEATURE>
<POSITION>0</POSITION>
<CLASS/></ATTRIBUTE>
```

- Takes comment annotations as instances, and classifies them using the rating feature.

- The classes (values of the rating features) form an unordered set (current limitation of the PR).

Batch learning config (3)

```
<NGRAM>
<NAME>ngram</NAME>
<NUMBER>1</NUMBER>
<CONSNUM>1</CONSNUM>
<CONS-1>
    <TYPE>Token</TYPE>
    <FEATURE>root</FEATURE>
</CONS-1>
</NGRAM>
```

- Uses unigrams of *Token.root* features inside the comment annotations as the instance attributes (bag of words).

- An additional feature in the hands-on file is commented out for you to experiment with later.

Building the training application (1)

- Create the following PRs with the default init parameters:
    - Document Reset PR
    - Annotation Set Transfer
    - ANNIE English Tokeniser
    - ANNIE Sentence Splitter
    - ANNIE POS Tagger
    - GATE Morphological Analyser
- Create a Batch Learning PR with the configFileURL init parameter set to the new location of your **paum.xml** file
- Create a new Conditional Corpus Pipeline.

Building the application (2)

- We want to copy the comment annotations to the default annotation set to provide the ML instances and classes

- We want to make sure we don't remove the Key annotations

- Add the PRs to the pipeline as follows
    - Document Reset:
        - setsToKeep = "Key"
    - Annotation Set Transfer:
        - annotationTypes = [comment]
        - copyAnnotations = true
        - inputASName = "Key"
        - outputASName, tagASName, textTagName = ""

Building the application (3)

- Add the remaining loaded PRs to the pipeline

    - English tokeniser

    - Sentence splitter

    - POS tagger

    - Morphological analyser

    - Batch Learning:

        - inputASName, outputASName = ""

        - learningMode = TRAINING

- Run it on the training corpus (this should take less than 1 minute)

- The classifier's model is stored in the **savedFiles** directory beside the **paum.xml** file. The model is stored in text files, but they are not meant to be human-readable.

Applying the training model (1)

- Create a "testing" corpus and populate it from the **corpora/testing** directory.

- To apply the classifier, we need to have comment annotations *without* rating features on the default AS. These will give us the instances to classify. A simple JAPE Transducer can do this.

- Load the grammar resources/grammar/copy_comment_spans.jape.

- Insert the grammar in the pipeline after the AS Transfer PR.

- Set the transducer parameters:

    - inputASName = "Key"

    - outputASName = ""

Applying the training model (2)

- Set the AS Transfer PR's run-mode to "no" (red light)

- Set the Batch Learning PR's parameters:

  - inputASName = ""

  - learningMode = APPLICATION

  - outputASName = "Output"

- The classifier will get instances (*comment* annotations) and attributes from the default AS and put instances with classes (*rating* features) in the Output AS.

Applying the training model (3)

- Run the pipeline on the testing corpus

- Open a few documents and inspect the "comment" annotations:

    - Key set = user ratings

    - default set = instances with no classes

    - Output set = instances with ML classes

Annotation Results

Evaluation: Precision and Recall

- On the test corpus, click the Corpus Quality Assurance tab.

- Select

    - Annotation Sets A = *Key*, B = *Output*

    - Annotation Types = *comment*

    - Annotation Features = *rating*

    - F-Score = F1.0-score strict

- Click "Compare"

- If every instance has been classified, then the total P = R = F1, because every spurious classification is paired with a missing classification

- Use the "Document statistics" sub-pane of Corpus QA to confirm this, and to see how specific documents were annotated

Corpus QA parameters

Results

Annotation	Match	Only A	Only B	Overlap	Rec.B/A	Prec.B/A	F1.0-s.
comment	79	20	20	0	0.80	0.80	0.80
Macro summary					0.80	0.80	0.80
Micro summary	79	20	20	0	0.80	0.80	0.80

Tabs: Corpus statistics | Document statistics

Evaluation: Cohen's Kappa

- Click on Measures in the Corpus QA settings and select "Classification", then Cohen's Kappa, and click "Compare".

- In addition to the document statistics with summary lines, there is now a "Confusion Matrices" sub-pane.

- The confusion matrix shows how many of each class were classified in that class (or in other classes)

- Cells in these tables can be selected with the mouse (or Ctrl-A to select all) and copied with Ctrl-C, so you can paste them into a spreadsheet.

Built-in cross-validation

- Cross-validation is a standard way to "stretch" the validity of a manually annotated corpus, because it enables you to test on a larger number of documents

- The 5-fold averaged result is more significant than the result obtained by training on 80% of the same corpus and testing on 20% once.

- In GATE, you can't use the Corpus QA tool on the result, but you can get a detailed statistical report at the end, including P, R, & F1 for each class.

Built-in cross-validation

- The config file includes:

  - <EVALUATION method="kfold" runs="5" ratio="0.66" />

  - kfold ignores the ratio setting

  - holdout ignores the runs setting

- The Batch Learning PR will automatically split the corpus into 5 parts, and then

  - train on 1,2,3,4; apply on 5; then

  - train on 1,2,3,5; apply on 4; …

  - train on 2,3,4,5; apply on 1;

  - and average the results.

Built-in cross-validation

- The application can be modified slightly to perform cross-validation according to the config file

- Switch the AS Transfer PR back on (so it copies the comment annoation to the default AS)

- Switch off the JAPE transducer

- Set the Batch Learning PR parameters:

  - inputAS, outputAS = ""

  - learningMode = EVALUATION

- Create a new corpus "all" and populate it from the **corpora/all** directory (all the documents from training and testing.)

- Run the pipeline on the new corpus. This will take a few minutes.

- Click on the Messages pane to view the results

Results

```
*** Averaged results for each label over 5 runs as:

Results of single label:
0 LabelName=1_Star_Review, number of instances=27
  (correct, partialCorrect, spurious, missing)= (1.6, 0.0, 0.6, 5.2);  (precision, recall, F1)= (0.4666667,
0.25333333, 0.3277778);  Lenient: (0.4666667, 0.25333333, 0.3277778)
1 LabelName=2_Star_Review, number of instances=6
  (correct, partialCorrect, spurious, missing)= (0.0, 0.0, 0.0, 1.6);  (precision, recall, F1)= (0.0, 0.0, 0.0);
 Lenient: (0.0, 0.0, 0.0)
2 LabelName=3_Star_Review, number of instances=17
  (correct, partialCorrect, spurious, missing)= (0.8, 0.0, 0.0, 3.6);  (precision, recall, F1)= (0.4,
0.24000001, 0.26666665);  Lenient: (0.4, 0.24000001, 0.26666665)
3 LabelName=4_Star_Review, number of instances=92
  (correct, partialCorrect, spurious, missing)= (1.8, 0.0, 3.4, 21.2);  (precision, recall, F1)=
(0.44666666, 0.0984191, 0.1436075);  Lenient: (0.44666666, 0.0984191, 0.1436075)
4 LabelName=5_Star_Review, number of instances=298
  (correct, partialCorrect, spurious, missing)= (72.8, 0.0, 29.4, 1.8);  (precision, recall, F1)=
(0.71384054, 0.9741704, 0.819043);  Lenient: (0.71384054, 0.9741704, 0.819043)

Overall results as:
  (correct, partialCorrect, spurious, missing)= (77.0, 0.0, 33.4, 33.4);  (precision, recall, F1)=
(0.6971326, 0.6971326, 0.6971326);  Lenient: (0.6971326, 0.6971326, 0.6971326)

Looking into the future

- Typically, opinion mining looks at social media content to analyse people's explicit opinions about a product or service

- This backwards-looking approach often aims primarily at dealing with problems, e.g. unflattering comments

- A forwards-looking approach aims at looking ahead to understanding potential new needs from consumers

- This is not just about looking at specific comments, e.g. "the product would be better if it had longer battery life", but also about detecting non-specific sentiment

- This is achieved by understanding people's needs and interests in a more general way, e.g. drawing conclusions from their opinions about other products, services and interests.

The problem of sparse data

- One of the difficulties of drawing conclusions from traditional opinion mining techniques is the sparse data issue

- Opinions tend to be based on a very specific product or service, e.g. a particular model of camera, but don't necessarily hold for every model of that brand of camera, or for every product sold by the company

- One solution is figuring out which statements can be generalised to other models/products and which are specific

- Another solution is to leverage sentiment analysis from more generic expressions of motivation, behaviour, emotions and so on, e.g. what type of person buys what kind of camera?

Summary

- Introduced the concept of Opinion Mining and Sentiment Analysis

- Simple examples of rule-based and ML methods for creating OM applications

- Examples of how deeper linguistic information can be useful

- Practice with complex applications

- Looking ahead to the future

More information

- See the following paper for details and evaluation of a more complex version of the twitter application

- D. Maynard and A. Funk. Automatic detection of political opinions in tweets. In Proceedings of MSM 2011: Making Sense of Microposts. Workshop at 8th Extended Semantic Web Conference (ESWC 2011). Heraklion, Greece. June 2011 (download PDF)

- The EU-funded ARCOMEM project is dealing with lots of issues about opinion mining from social media, and uses GATE for this. See http://www.arcomem.eu for more details

Suggestions for

further ML experiments...

Suggestions...

- The config file URL is an init parameter, but the contents can be re-loaded, so you can

    - use any text editor on the config file, save the changes, and

    - re-initialize the Batch Learning PR to re-load the file with changes.

Suggestions...

- Try n-grams where n>1
    - Change <NUMBER> in the config
    - Usually this is slower, but sometimes it improves quality
- combining features
    - change <CONSUM> in the config to 2 and uncomment the *Token.orth* element
    - this concatenates the features

Suggestions...

- Adjust the thresholdProbabilityClassification

  - Increasing it may increase precision and decrease recall, and may prevent the classifier from assigning a class to every instance.

  - Decreasing it may increase recall and decrease precision.

  - This is the "pickiness" control of the classifier.

Suggestions...

- Try using other features
    - *Token.string*, *Token.category*, or combinations of these with *Token.root* and *Token.orth*
- You could even include other ANNIE PRs in the pipeline and use Lookup or other annotation types.
    - You need to run the same annotation-creating PRs for training and application.
    - If the config file specifies an annotation that is missing in an instance, the ML PR will throw an exception.
